Security

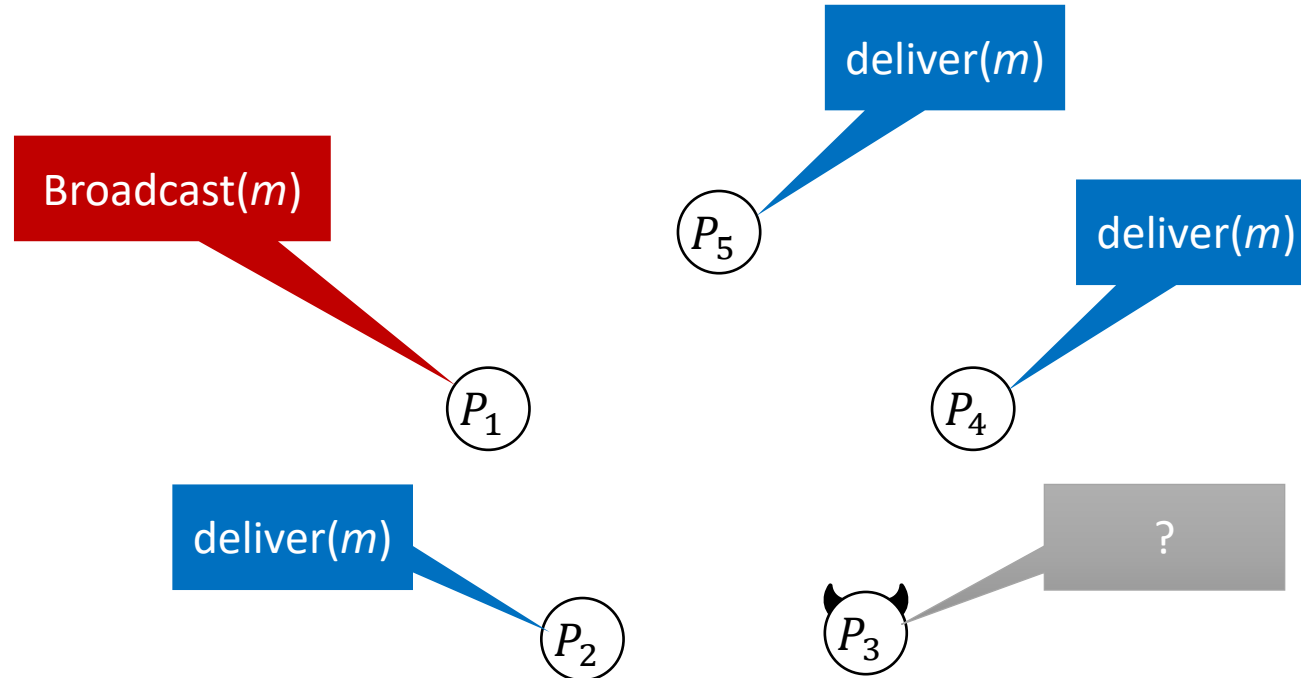

# (Crypto) Currency

# How to prevent double spendings?

- Shared view of everyone's balance
  - Centralized DB (bank)
  - Replicated state (e.g., blockchain)
- Consistent views of everyone's balance
  - Reliable broadcast [[Guerraoui et al. 2019](#)]

# Reliable Broadcast (multi-instance)

$$m = (\underbrace{\langle origin, tag \rangle}_{\langle instance \rangle}, \langle value \rangle)$$

# Reliable Broadcast (multi-instance)

- Integrity
  - If non-faulty Q delivers m with non-faulty origin P **then** P called broadcast(m).
- Validity
  - If non-faulty P broadcast m, **then** all non-faulty will deliver m
- Consistency
  - If non-faulty Q and R deliver  $m=(P,t,v)$  and  $m'=(P,t,v')$  **then**  $v=v'$  (even if P is faulty)
- Totality
  - If non-faulty Q receives m **then** any non-faulty R will receive m

# Reliable Broadcast cont.

- Available when #faulty  $< n/3$
- Message complexity  $\Theta(n^2)$  [Dolev et al 1985] [Bracha 1987]

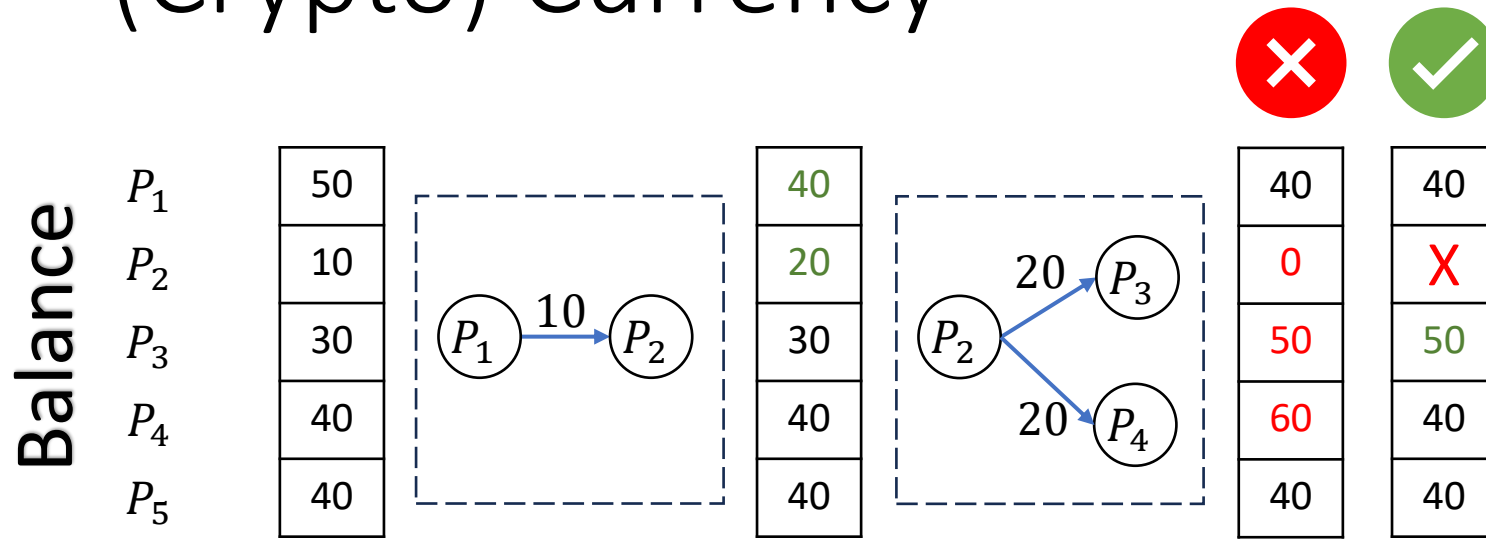

*Bracha G. Asynchronous Byzantine Agreement Protocols, INFORMATION AND COMPUTATION 75, 130-143 (1987)*

# Reliable Broadcast cont.

- Available when #faulty  $< n/3$
- Message complexity  $\Theta(n^2)$  [Dolev et al 1985] [Bracha 1987]
- Can prevent double spending!
  - by forcing per sender ordering

# (Crypto) Currency

$$m = (P_2, 1, P_2 \xrightarrow{20} P_3)$$

$$m' = (P_2, 1, P_2 \xrightarrow{20} P_4)$$

# Reliable Broadcast cont.

- Available when #faulty < n/3
- Message complexity  $\Theta(n^2)$  [Dolev et al 1985] [Bracha 1987]
- Can prevent double spending!
  - by forcing per sender ordering
  - Only one message per process and index will be received

$$m = (P_2, 1, P_2 \xrightarrow{20} P_3)$$

$$m' = (P_2, 1, P_2 \xrightarrow{20} P_4)$$

# Reliable Broadcast cont.

- Available when #faulty  $< n/3$
- Message complexity  $\Theta(n^2)$
- Can prevent double spending!

Can we improve it?

What if we had a trusted set?

# Reliable broadcast with trusted witness sets (quorums)

- Each message is sent and/or verified by the witness set
- Message complexity:  $\Theta(w \cdot n)$  where  $w$  is the witness set size.

This work (extended protocol)

# Reliable broadcast with trusted witness sets (quorums)

- Each message is sent and/or verified by the witness set
- Message complexity:  $\Theta(w \cdot n)$  where  $w$  is the witness set size.
- Challenges:
  - How to select such witness sets?
  - How to prevent an adaptive attacker from compromising them?

Idea: select a random set per message/transaction

# Random selection of witness sets

- Benefits
  - The witness set has similar ratio of faulty members like in the network W.H.P
  - Unpredictable and therefore hard to compromise in advance
- Existing approaches
  - MPC of shared randomness – high complexity
  - Use previous blockchain block hash [Algorand] – requires synchronous blocks
- **Goal: Random selection for high-rate transactions**

# Our approach: locality sensitive history hash

- Independently computed by each process (no communication latency)
- Similar histories are hashed to similar values (weak synchronization)
- Similar hash values results with similar (heterogenous) sets

# Our approach: locality sensitive history hash

- Challenges

- Histories may differ by some recent messages and the total ordering
- Hash should be hard to predict
- Quickly converge to uniform (compared to attack time)

- Solution

- History is hashed to a vector  $\mathbf{v}$  in a cyclic  $D$  dimensional space  $\mathbb{Z}_r^D$  (torus)
- Each message is hashed to dimension  $d \in [D]$  and a direction  $t \in \{-1, 1\}$ , and used to update  $\mathbf{v}[d] += t$
- Peer IDs are also hashed to the same hash space
- Peers are selected based on proximity to the history hash (at a given time)

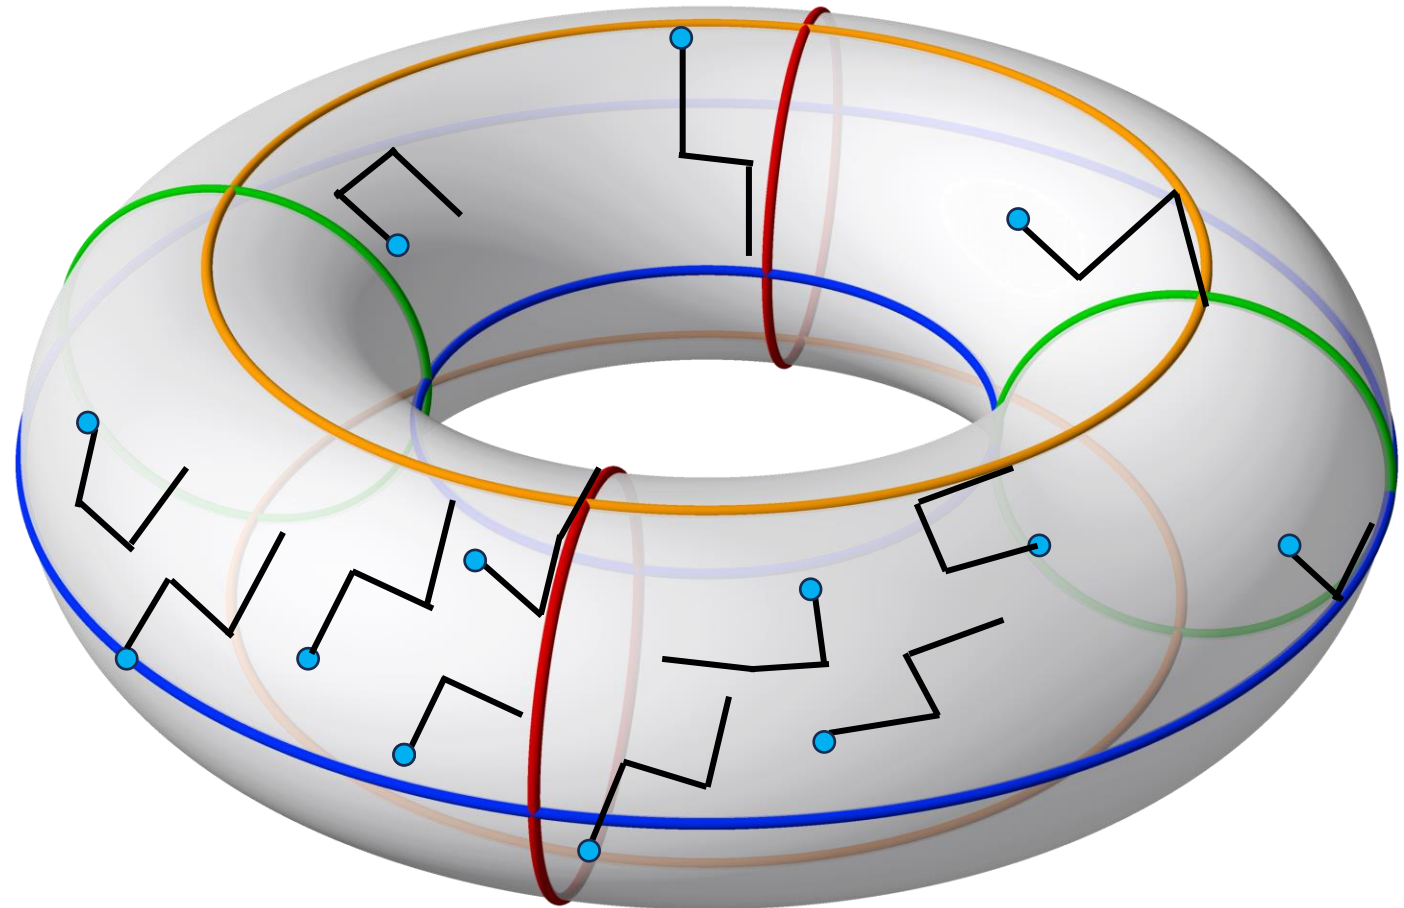

# Random walk in a torus

- History advances like a random walk in a torus.
- Peers are uniformly scattered.

# Random walk in a torus

- History advances like a random walk in a torus.
- Peers are uniformly scattered.
- Extension:  
History hash is used to derive independent per peer and transaction random walks

Technical Report: “Dynamic Probabilistic Reliable Broadcast” [[arxiv.org/abs/2306.04221](https://arxiv.org/abs/2306.04221)]

# Can we trust these witness sets?

- Reliable broadcast requirements are provided W.H.P
- Probability that a witness set is comprised is very low

$$\Pr(\text{faulty}(W) < k) = \sum_{i=0}^{k-1} \binom{f}{i} p^i (1-p)^{f-i}$$

- Time till many compromised peers are selected together is very large

- (Simulation + approximation)

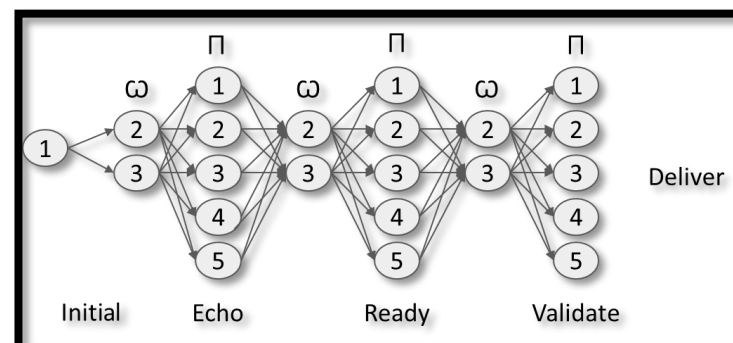

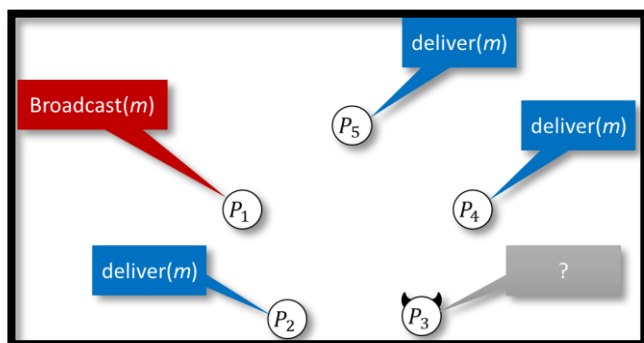

# Can we use external sources of trust?

- Adaptive witness set size based on message issuer (float trust)
  - Trust can be defined by  $\{p_i\}_{i \in [n]}$ 
    - where  $p_i$  = probability that  $i$  will try double spending
  - We can keep a constant failure probability
    - $p_{fail} = p_i \cdot Pr(\#faulty(W_i) > k)$
  - Faster transactions within trust cliques
- Extending witnesses with trusted peers (Boolean trust)
  - Considering
    - logarithmic size witness set ( $w = c \ln n$ )
    - Constant trust ratio  $T$  (each peer trusts  $T \cdot n$  peers)
    - Each peer uses the random set but if needed it also uses an extra (closest) trusted peer
  - Most of the times the random set can be trusted as is (constant number of extra peers)
  - Whenever  $T \geq 1 - e^{-\frac{1}{c}}$ , for example, if  $c = 1$  and  $T > \frac{2}{3}$  or  $c = 10$  and  $T > \frac{1}{10}$

# Summary

- Crypto currency using reliable broadcast
- Low-cost reliable broadcast using trusted witness sets
- Random selection of witnesses using local sensitive hashing of history
- Using external sources of trust

# Thank you

In memory of Israeli men, women and children slaughtered by Hamas and wishing for the release of all those abducted and still held in Gaza.
